Fast Fourier Transforms

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms The  $l_p$  norm of an *n*-vector  $\vec{v}$  is

$$||\vec{\mathbf{v}}||_{p} = \left(\sum_{k=1}^{n} |\mathbf{v}_{k}|^{p}\right)^{1/p}$$

Let  $S = \{(x_k, y_k)\}_{k=1}^n$  be a set of discrete data points derived from an unknown function *f* and let *g* be a function with parameters  $\{a_j\}_{j=1}^m$ . We say that *g* approximates *f* (or the data set) with  $I_p$  error of

$$E_p(a_1, a_2, ..., a_m) = \sum_{k=1}^n |y_k - g(x_k)|^p$$

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

## Examples

## Example 1

Suppose the approximating function is  $g(x) = a_1 e^{a_2 x} + a_3$ . Then the  $l_1$  error would be

$$E_1(a_1, a_2, a_3) = \sum_{k=1}^n |y_k - (a_1 e^{a_2 x_k} + a_3)|.$$

Finding the best fit parameters in an absolute sense would require minimizing the  $I_{\infty}$  error:

$$E_{\infty}(a_1, a_2, a_3) = \max_{1 \le k \le n} \{ |y_k - (a_1 e^{a_2 x_k} + a_3)| \}.$$

Both of these error functions lead to difficult minimization problems.

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Square Error

The Euclidean or Square error function,

$$E \equiv E_2(a_1,...,a_m) = \sum_{k=1}^n (y_k - g(x_k))^2,$$

is the commonly used error function because of it's convenient minimization properties and the following:

Theorem 2

(From Analysis) For all  $p, q \in \mathbb{Z}^+ \cup \{\infty\}$  and all  $n \in \mathbb{Z}^+$ , there exist  $m, M \in \mathbb{R}^+$  such that for all  $\vec{v} \in \mathbb{R}^n$ ,

$$m||\vec{v}||_{p} \leq ||\vec{v}||_{q} \leq M||\vec{v}||_{p}.$$

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Linear Least-Squares Approximation

Suppose that  $\{\phi_j\}_{j=1}^m$  are a set of "basis" functions and  $g(x) = a_1\phi_1(x) + a_2\phi_2(x) + ... + a_m\phi_m(x)$ . Then *g* approximates a data set *S* with square error given above. To minimize this error we solve the system

$$rac{\partial E}{\partial a_j} = 0, \ 1 \leq j \leq m$$

of linear equations.

### Example 3

Straight-line, linear least-squares approximation uses  $g(x) = a_1x + a_2$  as the approximating function.

Discrete Least Squares Approximation

## Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

## **Function Norms**

Suppose  $f \in C[a, b]$ , then the  $L_p$  norm of f is given by

$$||f||_{p} = \left(\int_{a}^{b} |f(x)|^{p} dx\right)^{1/p}$$

.

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Suppose *g* is an approximating function for *f*. Then the  $L_p$  error between *f* and *g* is

$$E_p = \int_a^b |f(x) - g(x)|^p \, dx$$

where g (and then  $E_p$ ) may depend on parameters  $a_1$ ,  $a_2$ , ...,  $a_m$ .

Dr. White

Discrete Least Squares Approximation

## Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Square Error for Functions

As with the discrete case, the common error that is used for functions is the **square error**, when p = 2.

### Example 4

Suppose g is an  $m^{th}$  degree polynomial. Then the square error is

$$E \equiv E_2(a_0,...,a_m) = \int_a^b \left(f(x) - \sum_{k=0}^m a_k x^k\right)^2 dx.$$

To minimize this error over the parameter space we solve the linear system of **normal equations**:

$$\frac{\partial E}{\partial a_k} = 0, \ k = 0, 1, ..., m.$$

#### Dr. White

Discrete Least Squares Approximation

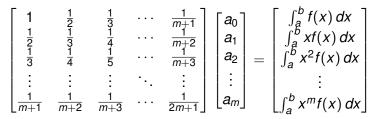

## Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Hilbert Matrix

### The above system of normal equations leads to:

The coefficient matrix is called a **Hilbert matrix**, which is a classic example for demonstrating round-off error difficulties.

#### Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Linear Independence of Functions

Definition 5 A set of functions  $\{f_1, f_2, ..., f_n\}$  is said to be **linearly independent** on [a, b] if

$$a_1f_f(x) + a_2f_2(x) + \cdots + a_nf_n(x) = 0, \ \forall x \in [a,b]$$

$$\Leftrightarrow a_1 = a_2 = \cdots = a_n = 0.$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Otherwise the set of functions is **linearly dependent**.

### Example 6

Is  $\{1, x, x^2\}$  linearly independent? How about  $\{1, \cos(2x), \cos^2(x)\}$ ?

Dr. White

Discrete Least Squares Approximation

### Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Orthogonal Functions and L<sub>2</sub> Inner Product

## Definition 7

Let  $f, g \in C[a, b]$ . The  $L_2$  inner product of f and g is given by

$$\langle f,g\rangle = \int\limits_{a}^{b} f(x)g(x)\,dx.$$

Note that the  $L_2$  norm of *f* is then  $||f||_2 = \sqrt{\langle f, f \rangle}$ .

### **Definition 8**

Two functions *f* and *g*, both in C[a, b], are said to be **Orthogonal** if  $\langle f, g \rangle = 0$ .

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Weighted Inner Products

## Definition 9

An integrable function w is called a weight function on the interval I if  $w(x) \ge 0$ , for all x in I, but  $w(x) \ne 0$  on any subinterval of I.

The purpose of a weight function is to assign more importance to approximations on certain portions of the interval.

## **Definition 10**

For f and g in C[a, b] and w a weight function on [a, b],

$$\langle f,g\rangle_w = \int\limits_a^b w(x)f(x)g(x)\,dx$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

is a weighted inner product.

Dr. White

Discrete Least Squares Approximation

#### Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Weighted Errors

The error function associated with a weighted inner product is

$$E(a_0,...,a_m) = \int_{a}^{b} w(x) (f(x) - g(x))^2 dx$$

where the approximating function g depends on the parameters  $a_k$ .

## Example 11

Suppose  $\{\phi_0, \phi_1, ..., \phi_m\}$  is a set of linearly independent functions on [a, b] and w is a weight function for [a, b]. Given  $f \in C[a, b]$ , we want to find the best fit approximation

$$g(x)=\sum_{k=0}^m a_k\phi_k(x).$$

#### Dr. White

Discrete Least Squares Approximation

## Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

## **Example Continued**

That is, we wish to minimize the above error. This leads to a system of normal equations of the form

$$\langle f, \phi_j \rangle_{\mathbf{w}} = \sum_{k=0}^m a_k \langle \phi_k, \phi_j \rangle_{\mathbf{w}}.$$

If we can choose the functions in  $\{\phi_0, \phi_1, ..., \phi_m\}$  to be pairwise orthogonal (with respect to the weight *w*), then the minimizing parameters would be given by

$$a_k = \frac{\langle f, \phi_k \rangle_w}{\langle \phi_k, \phi_k \rangle_w}.$$

**Rational Function Approximation** 

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Fast Fourier Transforms

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms Why?

Polynomials are good in that:

- Any continuous function can be approximated on a closed interval to within an arbitrary tolerance.
- Polynomials are easy to evaluate at arbitrary values.
- The derivatives and integrals of polynomials exist and are easy to determine.

Polynomials do tend to oscillate dramatically. So in discrete approximations, the approximating polynomial may have small  $l_2$  error even though the  $L_2$  error between the polynomial and the underlying function is large. Polynomials do not do well with discontinuities, especially singularities.

#### Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

#### Rational Function Approximation

Fast Fourier Transforms

# **Rational Functions**

### A rational function of degree N has the form

I

$$r(x)=\frac{p(x)}{q(x)}$$

where

$$p(x) = p0 + p_1 x + ... + p_n x^n$$

and

$$q(x) = q_0 + q_1 x + \ldots + q_m x^m$$

with n + m = N.

Rational functions often do a better job of approximating functions (with the same effort) as polynomials, and can include discontinuities. Note that, without loss of generality, we may set  $q_0 = 1$ .

#### Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Padé Approximation

This is an extension of Taylor polynomials to rational functions. It chooses parameters so that  $f^{(k)}(0) = r^{(k)}(0)$  for k = 0, 1, ..., N. When n = N and m = 0, the Padé approximation is simply the  $N^{th}$  degree Maclaurin polynomial.

Suppose f(x) has a Maclaurin expansion:  $f(x) = \sum a_i x^i$ . Then

$$f(x) - r(x) = rac{f(x)q(x) - p(x)}{q(x)} \ = rac{\sum\limits_{i=0}^{\infty} a_i x^i \sum\limits_{i=0}^{m} q_i x^i - \sum\limits_{i=0}^{n} p_i x^i}{q(x)}.$$

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ ● ●

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Minding the p's and q's

The objective is to find the constants  $p_i$  and  $q_i$  so that

$$f^{(k)}(0) - r^{(k)}(0) = 0$$
 for  $k = 0, 1, ..., N$ .

This means f - r has a root of multiplicity N + 1 at x = 0. That is, the numerator of f(x) - r(x) has no non-zero terms of degree less than N + 1. So,

$$\sum_{i=0}^{k} a_i q_{k-i} - p_k = 0$$

where we set  $p_i = 0$  for i = n + 1, n + 2, ..., N and  $q_i = 0$  for i = m + 1, m + 2, ...N.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Example

## Example 14

Find the Padé approximation for  $e^{-x}$  of degree 5 with n = 3 and m = 2.

Solution: expand the following and collect terms, setting coefficients of  $x^j$  to zero for j = 0, 1, ..., 5.

$$\left(1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \dots\right) \left(1 + q_1 x + q_2 x^2\right)$$
$$- \left(p_0 + p_1 x + p_2 x^2 + p_3 x^3\right).$$
To get  $p_0 = 1, p_1 = -\frac{3}{5}, p_2 = \frac{3}{20}, p_3 = -\frac{1}{60}, q_1 = \frac{2}{5}, \text{and}$ 
$$q_2 = \frac{1}{20}.$$

Fast Fourier Transforms

#### Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

$$e^{ix} = 1 + (ix) + \frac{(ix)^2}{2!} + \frac{(ix)^3}{3!} + \frac{(ix)^4}{4!} + \frac{(ix)^5}{5!} + \dots$$
$$= \left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots\right) + i\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots\right)$$
$$= \cos(x) + i\sin(x),$$

where  $i = \sqrt{-1}$ . So we can write

Euler's Formula

$$a_k\cos(kx)+b_k\sin(kx)=c_ke^{kx},$$

▲ロ▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

where  $a_k$  and  $b_k$  are real, and  $c_k$  is complex.

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# **Trigonometric Polynomials**

Given 2*m*, evenly spaced, data points  $\{x_j, y_j\}$  from a function *f*, we can transform the data in a linear way so that it is assumed that  $x_j = -\pi + (j/m)\pi$  for j = 0, 1, 2, ..., 2m - 1. Then we can find  $a_k$  and  $b_k$  so that

$$S_m(x) = \frac{a_0 + a_m \cos(mx)}{2} + \sum_{k=1}^{m-1} \left( a_k \cos(kx) + b_k \sin(kx) \right)$$

interpolates the transformed data. That is, when

$$a_k = \frac{1}{m} \sum_{j=0}^{2m-1} y_j \cos(kx_j)$$
 and  $b_k = \frac{1}{m} \sum_{j=0}^{2m-1} y_j \sin(kx)$ ,

the  $I_2$  error between  $S_m(x)$  and the data is zero.

#### Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

# Using Symmetry

Euler's formula gives us  $S_m(x) = \frac{1}{m} \sum_{k=0}^{2m-1} c_k e^{ikx}$  where  $c_k = \sum_{k=0}^{2m-1} y_j e^{ik\pi j/m}$ . From this we have  $a_k + ib_k = \frac{(-1)^k}{m} c_k$ . Suppose  $m = 2^p$  for some positive integer p, then for k = 0, 1, 2, ..., m - 1, we have

$$c_k + c_{m+k} = \sum_{j=0}^{2m-1} y_j e^{ik\pi j/m} (1 + e^{ij\pi}).$$

But  $1 + e^{ij\pi} = 2$  if *j* is even and zero if *j* is odd, so there are only *m* nonzero terms in the sum and we can write

$$c_k + c_{m+k} = 2 \sum_{l=0}^{m-1} y_{2l} e^{ik\pi(2l)/m} = 2 \sum_{l=0}^{m-1} y_{2l} e^{ik\pi l/(m/2)}$$

### Similarly,

Theory Dr. White

Chapter 3: Approximation

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

$$c_k - c_{m+k} = 2e^{ik\pi/m} \sum_{l=0}^{m-1} y_{2l+1} e^{ik\pi l/(m/2)}$$

Note that these two relationships allow us to calculate all of the  $c_k$ 's but the sums now require  $2m^2 + m$  complex multiplications instead of  $(2m)^2$  multiplications calculating the coefficients directly.

These sums have the same form as the sum for calculating the  $c_k$ 's directly except we replace m with m/2. Thus, we can repeat the process (another p - 1 times) to further reduce the number of complex multiplications to  $3m + m \log_2(m) = O(m \log_2(m))$ . If m = 1024, that is about 13,300 complex multiplications instead of about 4,200,000 using the direct method.

Dr. White

Discrete Least Squares Approximation

Orthogonal Polynomials

Rational Function Approximation

Fast Fourier Transforms

## Example

## Example 15

Play with Matlab to investigate FFT using functions like sin(nx) and cos(nx) for various values of  $n \in \mathbb{Z}^+$ . Then try  $f_1(x) = 1 - x^2$  and  $f_2(x) = x^3$  on [-1, 1]
